Re: Non-Provisional Utility Patent Application
Application No.: To be Assigned; Filed: February 24, 2000
For: **Liquid Crystal Display And A Method For Driving The Same**
Inventor(s): **Woon-Yong PARK and Haeng-Won PARK**
Our Ref: 06192.0100

Sir:

The following documents are forwarded herewith for appropriate action by the U.S. Patent and Trademark Office:

1. Utility Patent Application Transmittal Form;
2. Fee Transmittal Form 1082 (duplicate); and
3. U.S. Utility Patent Application entitled:

Liquid Crystal Display And A Method For Driving The Same

and naming as inventor(s):

Woon-Yong PARK and Haeng-Won PARK

the application consisting of:

- a. a specification containing:
 - (i) 25 pages of description prior to the claims;
 - (ii) 6 pages of claims (20 claims); and
 - (iii) a one (1) page abstract;
 - b. 10 sheets of drawings: (Figs. 1-3, 4A, 4B, 5-8, 9A, 9B);
4. Claim for Priority under 35 U.S.C. § 119 in Utility Application (duplicate);
 5. Certified copy of Korean Priority Document Patent Appl. No. 99-6086;

HOWREY & SIMON

Assistant Commissioner for Patents
February 24, 1999
Page 2

6. Our check no. 324063 for \$690.00 to cover:

\$ 690.00 filing fee for patent application;

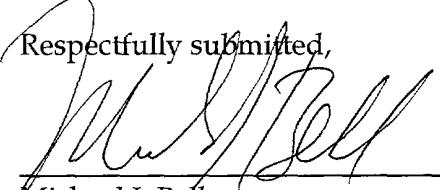

7. Two (2) return postcards.

It is respectfully requested that, of the two attached postcards, one be stamped with the filing date of these documents and returned to our courier, and the other, prepaid postcard, be stamped with the filing date and unofficial application number and returned as soon as possible.

Applicant hereby claims foreign priority benefits under Title 35, United States Code, § 119 to Korean Application No. 99-6086 filed February 24, 1999.

This application is being filed under 37 C.F.R. § 1.53(b) without an executed Declaration.

The U.S. Patent and Trademark Office is hereby authorized to charge any fee deficiency, or credit any overpayment, to our Deposit Account No. 08-3038. A duplicate copy of this letter is enclosed.

Respectfully submitted,

Michael J. Bell

ASSISTANT COMMISSIONER FOR PATENTS
Washington, D.C. 20231

Sir:

Transmitted herewith for filing is the patent application of
Inventor(s): **Woon-Yong PARK and Haeng-Won PARK**
For: **Liquid Crystal Display And A Method For Driving The Same**

Enclosed are:

- 10** sheets of drawings. (Figs. 1-3, 4A, 4B, 5-8, 9A, 9B)
- An assignment of the invention to **SAMSUNG ELECTRONICS CO., LTD.**
Form PTO-1595.
- A certified copy of Korean Patent Appl. 99-6086.
- An associate power of attorney.
- A verified statement to establish small entity status under 37 CFR 1.9 and 37 CFR 1.27.
- Executed Power of Attorney from Assignee.
- Executed Declaration for Patent Application.

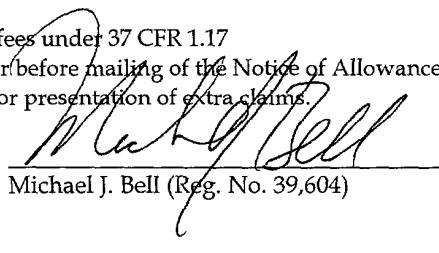

The filing fee has been calculated as shown below:

		(Col. 1)	(Col. 2)
FOR	NO. FILED	NO. EXTRA	
BASIC FEE			
TOTAL CLAIMS	20	-20 =	* 0
INDEP. CLAIMS	3	-3 =	* 0
<input type="checkbox"/> MULTIPLE DEPENDENT CLAIM PRESENTED			

SMALL ENTITY		OTHER THAN A SMALL ENTITY	
RATE	FEE	RATE	FEE
	\$ 380.00		\$ 690.00

**LIQUID CRYSTAL DISPLAY AND A METHOD
FOR DRIVING THE SAME**

BACKGROUND OF THE INVENTION

5 **(a) Field of the Invention**

The present invention relates to a liquid crystal display (LCD) and a method for driving the same. More specifically, the present invention relates to an LCD having its screen divided into two sections and driven individually, and a method for driving the same.

10 **(b) Description of the Related Art**

As personal computers and televisions become lighter in weight and thinner in profile, display devices must also become lighter in weight and thinner in profile. Accordingly, flat panel display devices such as LCDs are increasingly replacing the cathode ray tube (CRT).

15 In order to obtain desired image signals, the LCD applies an electric field to liquid crystal material having anisotropic dielectricity that is injected between two substrates, and controls the light amount permeating through the substrates by the intensity of the electric field. An LCD is one of the most commonly used portable flat panel display devices. In particular, a thin film
20 transistor liquid crystal display (TFT-LCD), employing the TFT as a switching element, is widely used.

The LCD comprises a plurality of gate lines that transmit scanning signals. A plurality of data lines crossing the gate lines transmit image data. And a plurality of pixels formed by regions defined by the gate lines and data

lines are interconnected through the gate lines, data lines and switching elements.

A method for applying the image data to each pixel in such an LCD will now be described.

5 When the scanning signals to turn on the gates (or gate-ON signals) are sequentially provided to the gate lines, the switching elements coupled to the gate lines are sequentially turned on. Image signals (i.e., data voltages) to be provided to pixel rows corresponding to the gate lines are concurrently provided to the respective data lines. The image signals provided to the data lines are
10 then applied to the respective pixels through the switching elements that have been turned on. At this time, by sequentially applying the gate-ON signals to all the gate lines during one frame period such that the image signals are applied to all the pixel rows, one frame of image is displayed.

A recently developed higher-resolution LCD requires more gate lines .
15 However, since the time for scanning a frame is limited to 1/60 of a second, the time interval of the gate-ON signal to be provided to the respective gate lines becomes shorter. Hence, it is difficult to provide sufficient image signals (i.e., the data voltages) to the image rows through the switching elements, which degrades the picture or image quality.

20 Therefore, a method has been disclosed recently to drive an LCD by dividing the display screen into two parts (an upper part and a lower part) in order to obtain a sufficient gate-ON time. Such a drive method is called a 'dual scan method'.

FIG. 1 shows an LCD adopting a dual scan method.

As shown in the drawing, the LCD using the dual scan method comprises a liquid crystal display (LCD) panel 10, an upper data driver 21, a lower data driver 22, an upper gate driver 31 and a lower gate driver 32.

The LCD panel 10 comprises a plurality of gate lines G1, G2, ..., Gm,
5 Gm+1, ..., G2m to transmit the gate-ON signals and a plurality of data lines D1,
D2, ..., Dn, C1, C2, ..., Cn to transmit the data voltages (i.e., image signals).

Regions defined by the crossing of the data lines and gate lines form pixels.

Each pixel comprises a TFT 12, a gate electrode of which is coupled to a gate
line and a source electrode of which is coupled to a data line, a pixel electrode

10 14 coupled to a drain electrode of the TFT 12 and a common electrode (not
illustrated) to which a common voltage is supplied. The plurality of gate lines
are divided into an upper gate line block and a lower gate line block, each
comprised of m gate lines, respectively G1, G2, .., Gm, and then, Gm+1, ...,
G2m. The data lines D1, D2, ..., Dn coupled to the pixels corresponding to the
15 gate lines G1, G2, ..., Gm of the upper gate line block are separated from the
data lines C1, C2, ..., Cn coupled to the pixels corresponding to the gate lines
Gm+1, ..., G2m of the lower gate line block. For example, an upper pixel of a
first column is coupled to the data line D1 and a lower pixel of the first column is
coupled to the data line C1.

20 The upper and lower gate drivers 31 and 32, coupled respectively to the
upper and lower gate line blocks, sequentially provide gate-ON voltages to the
gate lines of the upper and lower gate line blocks, respectively. At this time, the
gate-ON voltages are provided to the gate lines from the first gate line and to
the last gate line. The upper and lower data drivers 21 and 22, located

respectively in the upper part and lower part of the LCD panel, supply the data voltages to the upper data lines D₁, D₂, ..., D_n and the lower data lines C₁, C₂, ..., C_n, respectively.

The operation of the LCD will be described hereinafter.

5 The gate-ON signals are sequentially provided to the TFTs 12 from the gate lines of the upper and lower gate line blocks starting from the first gate line then to subsequent gate lines. Concurrently, the data voltages (i.e., image signals) are provided to the upper and lower data lines. The TFTs 12 are turned on by the gate-ON signals, and the data voltages supplied to the data lines are
10 provided to pixel electrodes through the TFTs 12 that are turned on. Electric fields generated by differences between the pixel voltages (i.e., the voltages supplied to the pixel electrodes) and the common voltages of the common electrodes are applied to the liquid crystal material. Since the arrangement of the liquid crystal material changes depending upon the intensity of the electric field (the intensity of the electric field varies according to the intensity of the data voltage), the amount of light permeating the liquid crystal material varies.
15 Therefore, desired images are displayed on the LCD.

Since the gate-ON signals are concurrently supplied to the gate lines in the upper and lower gate line blocks, the above described dual scan type LCD
20 has the advantage of a twice longer gate-ON time than the conventional single scan LCDs.

The electric field applied to the liquid crystal material continuously in the same direction deteriorates the liquid crystal material. Accordingly, when the data voltages are driven, the polarities of the data voltages are

alternated between positive and negative values. Such a drive method is referred to as an inversion drive method.

Among different types of inversion drive methods are a frame inversion drive method that alternates the polarities every frame; a line inversion drive method that alternates the polarities every line; and a dot inversion drive method that alternates the polarities every pixel. The line inversion and dot inversion drive methods are most commonly used. However, the line inversion drive method or dot inversion drive method, when applied to the conventional dual scan type LCD, causes various drawbacks as described below.

It is assumed that the pixel of the LCD in FIG. 1 are driven by the dot inversion drive method, as shown by the positive (+) and negative (-) indications. The positive (+) polarity indicates that the polarity of the pixel voltage with respect to the common voltage is positive, and the negative (-) polarity indicates that the polarity of the pixel voltage with respect to the common voltage is negative.

A waveform of a voltage applied to the pixel electrode electrically coupled to the gate line G_m of the upper gate line block and to the data line D₁, and a waveform of a voltage applied to the pixel electrode electrically coupled to the gate line G_{m+1} of the lower gate line block and to the data line C₁ are shown in FIG. 2.

As shown in FIG. 2 (a), in an ideal state, a voltage V_{pu} lower than the common voltage V_{com} is uniformly applied during a period of one frame to the pixel electrode of the first pixel row coupled to the last gate line G_m in the upper gate line block. However, in the actual LCD, since a parasitic capacitance is

generated between the pixel electrode and data line, the pixel voltage provided to the actual pixel electrode is affected by the voltage provided to the data line. That is, since the data voltages $Vd1$, the polarities of which with respect to the common voltage $Vcom$ are periodically alternated are provided to the first data line D1 as shown in FIG. 2 (a), the actual voltage Va provided to the pixel electrode becomes the waveform as shown in FIG. 2 (b). For ease of explanation, the data voltages are assumed to be symmetrical with respect to the common voltage $Vcom$.

In more detail, as illustrated in FIGs. 2 (a) and (b), in the case where a pixel voltage Vpu with a negative polarity is provided and then a data voltage Vd with a positive polarity is provided to the data lines, the actual pixel voltage Va , unlike the ideal pixel voltage Vpu , is pulled in the direction of the common voltage by as much as ΔV due to the parasitic capacitance. On the other hand, if a data voltage with a negative polarity is provided to the data lines, the actual pixel voltage Va is pulled in the opposite direction of the common voltage by as much as ΔV .

As shown in FIG. 2 (c), in the ideal case, a constant voltage Vpd , higher than the common voltage $Vcom$, is provided to a pixel electrode of a first pixel row coupled to the first gate line $Gm+1$ in the lower gate line block during one frame interval. Further, a data voltage with a polarity identical to that of the data voltage provided to the data line D1 is supplied to a first data line C1. This is because the scanning process begins from the first gate line of each of the upper gate line block and the lower gate line block and the polarities of the pixel

voltages coupled to the first gate line in the upper gate line block and lower gate line block are identical.

Therefore, because of the influence of the parasitic capacitance, the actual voltage provided to the pixel electrode has a waveform as shown in FIG.

5 2 (d). That is, as shown in FIGs. 2 (c) and (d), when the voltage V_{pd} with a positive polarity is provided and then the data voltage with a positive polarity is provided to the data lines, the actual pixel voltage V_b , unlike the ideal pixel voltage V_{pd} , is pulled in the opposite direction of the common voltage by as much as ΔV due to the parasitic capacitance. Also, if a data voltage with a
10 negative polarity is provided to the data lines, the actual pixel voltage V_b is pulled in the direction of the common voltage by as much as ΔV .

As a result, since the voltages provided to the data lines influence the pixels of the two pixel rows on the boundaries in the opposite directions, the actual difference between the voltage provided to the pixels and the common voltage becomes the area marked by oblique lines in FIGs. 2 (b) and (d). This makes a big difference in the amounts of the light permeating the liquid crystal material in the pixels at the boundaries of the upper block and the lower block, which results in the inconsistent brightness on the boundaries. Eventually, this appears as undesired lines at the boundaries between the upper block and the
15 lower block.
20

SUMMARY OF THE INVENTION

It is an object of the present invention to provide a liquid crystal display (LCD) and a method for driving the same by dividing the screen into two panels

and eliminates non-uniform luminance phenomena at the boundaries of the two panels.

In order to achieve this object, the LCD panel is divided into two panels - an upper panel and a lower panel. When providing scanning signals to gate lines, the scanning direction for the upper panel is opposite to that for the lower panel to prevent the non-uniformity of the luminance at the boundaries of the panels.

According to the present invention, a liquid crystal display (LCD) comprises a first gate line block including a plurality of first gate lines transmitting scanning signals, a second gate line block including a plurality of second gate lines transmitting scanning signals, scanning directions of the first gate lines being opposite to scanning directions of the second gate lines, a plurality of first data lines transmitting image signals and crossing the first gate lines of the first gate line block, a plurality of second data lines separated from the first data lines and crossing the second gate lines of the second gate line block, a plurality of pixels configured in a matrix pattern and defined by the gate lines and data lines, and including switching elements coupled to the gate lines and the data lines.

The number of the first gate lines is equal to the number of the second gate lines. The first gate lines and the second gate lines are simultaneously scanned.

According to the other aspect of the present invention, a liquid crystal display (LCD) comprises an LCD panel that includes a first gate line block having a plurality of first gate lines , a second gate line block formed beneath

the first gate line block and having a plurality of second gate lines, a plurality of first data lines crossing and separated from the first gate lines of the first gate line block, a plurality of second data lines crossing and separated from the second gate lines of the second gate line block, and a plurality of pixels formed
5 by areas defined by the gate lines and data lines, and arrayed in a matrix pattern, the pixels having switching elements coupled to the gate lines and the data lines, and common electrodes to which common voltage is supplied. The LCD further comprises a first data driver supplying data voltages, which contain
10 image signals, to the first data lines, a second data driver supplying data voltages, which contain image signals, to the second data lines, a first gate driver supplying scanning signals to the gate lines of the first gate line block, a second gate driver supplying scanning signals to the gate lines of the second gate line block in an opposite scanning direction as the first gate driver, a first frame memory receiving and writing external image signals in synchronization
15 with write clock signals, and outputting the image signals to the first data driver in synchronization with read clock signals, and a second frame memory receiving and writing external image signals in synchronization with the write clock signals, and outputting the image signals to the second data driver in synchronization with the read clock signals.

20 The number of the first gate lines is equal to the number of the second gate lines. The first gate driver and the second gate driver are simultaneously scanned. Polarities of the data voltages supplied to the pixels coupled to adjacent gate lines of the first gate line block are opposite to each other with respect to the common voltage, and the polarities of the data voltages supplied

to the pixels coupled to the neighboring gate lines of the second gate line block are opposite to each other with respect to the common voltage. The first gate driver sequentially supplies the scanning signals to the gate lines in the direction from the last gate line of the first gate line block to the first gate line,
5 and the second gate driver sequentially supplies the scanning signals to the gate lines in the direction from the first gate line of the second gate line block to the last gate line. The first frame memory outputs the image signals, which are written in a reverse order from the image signals to be provided to the first data lines, to the first data driver, and the second frame memory outputs the image
10 signals, which are written in the same order from the image signals to be provided to the second data lines, to the second data driver. The polarity of the common voltage, with respect to the data voltage supplied to the pixels coupled to the last gate line of the first gate line block, is opposite to that of the common voltage, with respect to the data voltage supplied to the pixels coupled to the
15 first gate line of the second gate line block on the identical pixel row. The polarity of the common voltage, with respect to the data voltage supplied to the pixels coupled to the last gate line of the first gate line block, is identical to that of the common voltage, with respect to the data voltage supplied to the pixels coupled to the first gate line of the second gate line block on the identical pixel
20 row. The first gate driver sequentially supplies the scanning signals to the gate lines in the direction from the first gate line of the first gate line block to the last gate line, and the second gate driver sequentially supplies the scanning signals to the gate lines in the direction from the last gate line of the second gate line block to the first gate line. The first frame memory outputs the image signals,

which are written in an order identical to the image signals to be provided to the first data lines, to the first data driver, and the second frame memory outputs the image signals, which are written in an order opposite to the image signals to be provided to the second data lines, to the second data driver. The polarity of
5 the common voltage, with respect to the data voltage supplied to the pixels coupled to the last gate line of the first gate line block, is opposite to that of the common voltage, with respect to the data voltage supplied to the pixels coupled to the first gate line of the second gate line block on the identical pixel row. The polarity of the common voltage with respect to the data voltage supplied to the
10 pixels coupled to the last gate line of the first gate line block, is identical to that of the common voltage, with respect to the data voltage supplied to the pixels coupled to the first gate line of the second gate line block on the identical pixel row.

In another aspect of the present invention, a method for driving a liquid crystal display (LCD) including a first gate line block having a plurality of first gate lines formed in a horizontal direction, a second gate line block formed beneath the first gate line block and having a plurality of second gate lines, a plurality of first data lines crossing and separated from the first gate lines of the first gate line block, and a plurality of second data lines crossing and separated
15 from the second gate lines of the second gate line block, comprises the steps of providing sequentially scanning signals to the first gate line of the first gate line block, providing sequentially scanning signals to the second gate line of the second gate line block in an opposite scanning direction to the first gate line,
20 and supplying data voltages, which contain image signals, to the first and

second data lines so that the data voltages are supplied to the pixels coupled to the gate lines to which the scanning signals are provided.

The scanning signals are sequentially provided to the first gate line block in the direction from the last gate line to the first gate line and to the second gate line block in the direction from the first gate line to the last gate line. The method further comprises the steps of writing the externally received image signals to be provided to the first data line to the first frame memory, , writing the externally received image signals to be provided to the second data line to the second frame memory, outputting the image signals to the first data lines in an opposite order as the image signals to be written to the first frame memory and outputting the image signals to the second data lines in an order opposite to the image signals to be written to the second frame memory. The scanning signals are sequentially provided to the first gate line block in the direction from the first gate line to the last gate line, and to the second gate line block in the direction from the last gate line to the first gate line. The method further comprises the steps of writing the externally received image signals to be provided to the first data line to the first frame memory, writing the externally received image signals to be provided to the second data line to the second frame memory, outputting the image signals to the first data lines in an opposite order as the image signals to be written to the first frame memory, and outputting the image signals to the second data lines in an order opposite to the image signals to be written to the second frame memory.

BRIEF DESCRIPTION OF THE DRAWINGS

The accompanying drawings, which are incorporated in and constitute a part of the specification, illustrate an embodiment of the invention, and, together with the description, serve to explain the principles of the invention.

5 FIG. 1 is an LCD configured for a dual scan method.

FIGs. 2 (a), (b), (c), and (d) are waveforms according to a conventional LCD driving method;

FIG. 3 is a schematic diagram of an LCD according to a preferred embodiment of the present invention;

10 FIGs. 4 (a) and (b) are timing diagrams of data input and output to and from a frame synchronized with writing and reading clock signals;

FIG. 5 is a circuit diagram illustrating polarities and scanning directions of the LCD shown in FIG. 3 according to a first embodiment of the present invention;

15 FIGs. 6 (a), (b), (c), and (d) are signal waveforms according to the first embodiment of the present invention;

FIG. 7 is a circuit diagram illustrating polarities and scanning directions of the LCD shown in FIG. 3 according to a second embodiment of the present invention;

20 FIGs. 8 (a), (b), (c), and (d) are signal waveforms according to the second embodiment of the present invention; and

FIGs. 9 (a) and (b) are circuit diagrams illustrating polarities and scanning directions of the LCD shown in FIG. 3 respectively according to third and fourth embodiments of the present invention.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

In the following detailed description, only the preferred embodiment of the invention has been shown and described, simply by way of illustrating the best mode contemplated by inventors of carrying out the invention. As will be realized, the invention is capable of modification in various obvious respects, all without departing from the invention. Accordingly, the drawings and description are to be regarded as illustrative in nature, and not restrictive.

FIG. 3 shows an LCD according to a preferred embodiment of the present invention.

The LCD comprises an LCD panel 100, an upper data driver 210, a lower data driver 220, an upper gate driver 310, a lower gate driver 320, a frame memory unit 400 including an upper frame memory 410 and a lower frame memory 420, and a timing controller 500.

The LCD panel 100 comprises 2m gate lines G1, G2, ..., G_{m+1}, ..., G_{2m} to transmit gate-ON signals, and data lines D1, D2, ..., D_n and C1, C2, ..., C_n to transmit the data voltages displaying image signals. Areas defined by the gate lines and data lines form pixels, and each pixel comprises, as shown in FIG. 5, a TFT 110, a gate line that is coupled to a gate electrode and a data line that is coupled to a source electrode, a pixel electrode 120 coupled to a drain electrode of the TFT 110, and a common electrode (not illustrated) to which a common voltage is supplied. The 2m gate lines are divided into an upper gate line block comprising m gate lines of G1, G2, ..., G_m and a lower gate line block comprising m gate lines of G_{m+1}, G_{m+2}, ..., G_{2m}. The upper data lines D1,

D2, ..., Dn coupled to pixels corresponding to the gate lines G1, G2, ..., Gm of the upper gate line block are separated from the lower data lines C1, C2, ..., Cn coupled to the pixels corresponding to the gate lines Gm+1, Gm+2, ..., G2m of the lower gate line block. That is, the LCD panel according to the embodiment of the present invention comprises an upper panel 140 and a lower panel 150. The upper panel 140 comprises the upper gate line block and upper data lines D1, D2, ..., Dn, and the lower panel 150 comprises the lower gate line block and the lower data lines C1, C2, ..., Cn.

The upper and lower gate drivers 310 and 320, each coupled to the upper and lower gate line blocks, sequentially supply gate-ON voltages to the gate lines of the gate line blocks in the opposite scanning directions. For example, when the upper gate driver 310 drives gate-ON voltages in the direction from the first gate line G1 of the upper gate line block to the mth gate line Gm (i.e., from the top to the bottom), the lower gate driver 320 drives the gate-ON voltages in the direction from the last gate line G2m of the lower gate line block to the first gate line Gm+1 (i.e., from the bottom to the top). As mentioned above, when the upper gate driver 310 sequentially supplies the gate-ON voltages to the gate lines in the direction from the bottom to the top, the lower gate driver 320 supplies the gate-ON voltages to the gate lines in the direction from the top to the bottom.

The upper data driver 210 and the lower data driver 220, located on the upper side and lower side of the LCD panel are coupled to the upper frame memory 410 and the lower frame memory 420. They respectively supply the

data voltages displaying the image signals to the upper data lines D1, D2, ..., Dn and the lower data lines C1, C2, ..., Cn.

The timing controller 500 receives image data signals DATA, main clocks MCLK, horizontal synchronization signals Hsync, and vertical synchronization signals Vsync, and provides timing signals to the frame memory unit 400, upper gate driver 310, lower gate driver 320, upper data driver 210, and lower data driver 220. The upper frame memory 410 and the lower frame memory 420, synchronized with write clock signals WCLK and read clock signals RCLK (the frequency of which is half the write clock signals WCLK provided from the timing controller 500), write and read the image data signals to be provided to the upper data driver 210 and the lower data driver 220.

The operation of the LCD according to the first embodiment of the present invention will be described hereinafter. FIGs. 4 (a) and (b) are data timing diagrams illustrating that the data synchronized with the write clock signals WCLK and read clock signals RCLK ($RCLK = WCLK/2$) are input and output to and from the frame memories.

The external image data signals DATA, main clocks MCLK, vertical synchronization signals Vsync (i.e., frame synchronization signals), and horizontal synchronization signals Hsync (i.e., synchronization signals of the horizontal lines or the scanning lines) are provided to the timing controller 500.

Referring to FIG. 4 (a), the frame memories are synchronized with the write clock signals WCLK provided from the timing controller 500 and write data. That is, data synchronized with the write clock signals WCLK are written to the upper frame memory 410 in order starting from the image data d1 to be

provided to the first pixel row. In this case, the image data d₁, d₂, ..., d_m to be provided to the pixel rows from the first pixel row to the mth pixel row (i.e., the pixel rows corresponding to the gate lines of the upper gate line block) are written on the upper frame memory 410. On the other hand, the image data,
5 synchronized with the write clock signals WCLK, starting from the image data d_{m+1}, to be provided to the pixel row corresponding to the first gate line G_{m+1} of the lower gate line block, to all subsequent image data d_{m+1}, d_{m+2}, ..., d_{2m} are sequentially written on the lower frame memory 420.

When all the image data to be provided to each pixel row are written on
10 the upper frame memory 410 and the lower frame memory 420, the image data synchronized with the read clock signals RCLK are transmitted to the upper data driver 210 or lower data driver 220 as shown in FIG. 4 (b). At this time, according to the first embodiment of the present invention, the image data for the upper data driver 210 are transmitted to the upper data driver 210 in an order opposite to that in which the upper frame memory 410 is written (i.e., d_m, d_{m-1}, d_{m-2}, ..., d₂, d₁). The image data for the lower data driver 220 are transmitted to the lower data driver 220 in an order identical to that in which the lower frame memory 420 is written. Therefore, according to the present invention, frame memories that can be addressed in a reverse order of writing
15 should be used.
20

When the image data synchronized with the clock signal HCLK are transmitted to the upper data driver 210 and the lower data driver 220, the image data are transformed into corresponding data voltages and provided to

each line of the upper data lines D1, D2, ..., Dn and lower data lines C1, C2, ...,

Cn according to load signals LOAD output from the timing controller 500.

The upper gate driver 310 and the lower gate driver 320 supply gate-ON signals (i.e., scanning signals), synchronized with start signals STV and gate

5 clocks CPV output from the timing controller 500, to the gate lines of the upper gate line block and concurrently to the gate lines of the lower gate line block. At this time, according to the first embodiment of the present invention, the upper gate driver 310 sequentially provides the gate-ON voltages from the last gate line Gm of the upper gate line block to the first gate line G1 of the upper gate line block (i.e., from the bottom to the top). And the lower gate driver 320 sequentially provides the gate-ON voltages to the first gate line GM+1 of the lower gate line block the last gate line G2m of the lower gate line block (i.e., from the top to the bottom).

The TFTs coupled to the gate lines to which the gate-ON voltages are

15 provided are turned on, and therefore, the data voltages provided to the data lines are transmitted to the pixel electrodes through the TFTs that are turned on, displaying desired images.

The above-described embodiment of the present invention can eliminate lines appearing at the center of the screen when driving the dual-scan

20 LCD using the dot inversion or line inversion methods.

FIG. 5 is a circuit diagram illustrating polarities and scanning directions of the upper gate driver 310 and the lower gate driver 320 according to the first embodiment of the present invention. FIGs. 6 (a), (b), (c) and (d) are signal waveforms according to the first embodiment of the present invention.

Referring to FIG. 5, (+) indicates that the polarity of a pixel voltage against the common voltage is positive, and (-) indicates that the polarity of a pixel voltage against the common voltage is negative. Two adjacent pixels in the first pixel row will be described as an example hereinafter.

5 Referring to FIG. 6 (a), in an ideal case, a voltage V_{pu} lower than the common voltage V_{com} applied to a pixel electrode of the first pixel row coupled to the last gate line G_m of the upper gate line block should remain uniform and constant during one frame. However, the parasitic capacitance between the pixel electrode and the data line has the actual pixel voltage provided to the
10 pixel electrode affected as a voltage for another pixel connected to the same data line is applied. That is, since the data voltages, the polarities of which are periodically alternated with reference to the common voltage, are provided to the first upper data line D_1 , the actual voltage V_a provided to the pixel electrode is as shown in FIG. 6 (b). At this time, since the gate line is scanned from the
15 bottom to the top and the polarity of the pixel electrode corresponding to the last gate line G_m of the first pixel row is negative, the data voltages provided to the data line D_1 alternate continuously between positive and negative as shown in FIG. 6 (a).

In more detail, referring to FIGS. 6 (a) and (b), when the pixel voltage
20 V_{pu} with a negative (-) polarity is supplied, and the data voltage with a negative (-) polarity is supplied to the data line, the actual pixel voltage V_a is, due to the influence of parasitic capacitance C_p , drawn to the opposite direction of the common voltage by as much as ΔV , compared to the ideal pixel voltage V_{pu} . On the other hand, when the data voltage of a positive (+) polarity is supplied to

the data line, the actual pixel voltage V_a is drawn to the direction of the common voltage by as much as ΔV .

Referring to FIG. 6 (c), in an ideal case, a voltage V_{pd} higher than the common voltage V_{com} is uniformly supplied to the pixel electrode of the first pixel row coupled to the first gate line G_{m+1} of the lower gate line block and it should remain uniform and constant during one frame period. Another data voltage with a polarity different from the data voltage supplied to the data line D_1 is supplied to the first lower data line C_1 , because, as shown by FIG. 5, the upper gate line block is scanned from bottom to top, the lower gate line block is scanned from top to bottom, and the pixel voltage V_{pu} coupled to the last gate line G_m of the upper gate line block is different from the first gate line G_{m+1} of the lower gate line block. Hence, the actual voltage supplied to the pixel electrode due to parasitic capacitance C_p has waveforms as shown in FIG. 6 (d). That is, referring to FIGs. 6 (c) and (d), when the pixel voltage V_{pd} with a positive (+) polarity is supplied, and the data voltage with a positive (+) polarity is supplied to the data line, the actual pixel voltage V_b is, due to the influence of parasitic capacitance C_p , drawn to the opposite direction of the common voltage by as much as ΔV compared to the ideal pixel voltage V_{pd} . When the data voltage of a negative (-) polarity is supplied to the data line, the actual pixel voltage V_b is drawn to the direction of the common voltage by as much as ΔV .

As described above, according to the first embodiment of the present invention, since the voltages provided to the data lines influence the pixels of the two pixel rows on the boundaries in the identical direction, the difference

between the voltage supplied to the actual pixels and the common voltage is as shown by the oblique lines in FIGS. 6 (b) and (d). Therefore, since a difference in the amount of light permeating the liquid crystal material on the pixels of the boundaries is small, the brightness on the boundaries becomes almost uniform.

- 5 Consequently, the line patterns appearing on the boundaries of the upper and lower panels in the conventional method of driving the dual scan LCD disappears.

An operation of the LCD according to a second embodiment of the present invention will now be described.

10 FIG. 7 is a circuit diagram illustrating polarities and scanning directions of the upper and lower gate drivers of the LCD according to the second embodiment of the present invention. FIG. 8 shows various signal waveforms according to the second embodiment of the present invention.

15 Referring to FIG. 7, the polarities of two adjacent pixels on the boundaries are identical to each other, and the polarities of other pixels on the boundaries are alternated. Two adjacent pixels on the first pixel row will be described as an example hereinafter.

Referring to FIG. 8 (a), in an ideal case, a pixel voltage V_{pu} higher than the common voltage V_{com} is uniformly supplied to the pixel electrode of the first pixel row coupled to the last gate line G_m of the upper gate line block and maintained uniform and constant during one frame period. However, the actual pixel voltage of the pixel electrode is influenced by the voltage subsequently supplied to the data line due to the parasitic capacitance C_p between the pixel electrode and the data line.

That is, since the data voltages, the polarity of which periodically alternates with respect to the common voltage, are supplied to the first upper data line D1, the voltage V_a supplied to the actual pixel electrode becomes as shown in FIG. 8 (b). At this time, since the gate lines are scanned from bottom 5 to top and the polarity of the pixel electrode corresponding to the last gate line G_m of the first pixel row is positive, the data voltages supplied to the data line D1 alternate between positive and negative as shown in FIG. 8 (a).

In more detail, as shown in FIGS. 8 (a) and (b), when the pixel voltage V_{pu} with a positive polarity is supplied and the data voltage with a positive 10 polarity is supplied to the data line, the actual pixel voltage V_a is drawn to the opposite direction of the common voltage by as much as ΔV , compared to the ideal pixel voltage V_{pu} as a result of parasitic capacitance. On the other hand, when the data voltage with a negative polarity is supplied to the data line, the pixel voltage V_a is drawn to the direction of the common voltage by as much as 15 ΔV .

Referring to FIG. 8 (c), in an ideal case, a pixel voltage V_{pd} higher than the common voltage V_{com} is supplied to the pixel electrode of the first pixel row coupled to the first gate line G_{m+1} of the lower gate line block and maintained uniform and constant during one frame period. The data voltage, which has an 20 identical polarity with the data voltage supplied to the data line D1, is supplied to the first lower data line C1, because, as shown in FIG. 7, the upper gate line block is scanned from bottom to top, the lower gate line block is scanned from top to bottom, and the polarity of the pixel voltage coupled to the last gate line G_m of the upper gate line block is identical to the polarity of the pixel voltage

coupled to the first gate line G_{m+1} of the lower gate line block. Therefore, the voltage supplied to the actual pixel electrode has waveforms as shown in FIG. 8 (d).

Referring to FIG. 8, according to the second embodiment of the present invention, since the voltages provided to the data lines influence the pixels of the two pixel rows on the boundaries in the identical direction, the difference between the actual voltage of the pixels and the common voltage is as shown by the oblique lines in FIGs. 8 (b) and (d). Therefore, since the difference in the amount of light permeating the liquid crystal material on the pixels of the boundaries is small, the brightness on the boundaries becomes almost uniform. Consequently, the conventional line patterns generated at the boundaries of the upper panel and the lower panel do not appear.

In the above embodiment of the present invention, the gate line coupled to the upper gate driver is scanned from bottom to top, and the gate line coupled to the lower gate driver is scanned from top to bottom.

However, the driving method for the LCD according to the present invention also includes an embodiment where the gate line coupled to the upper gate driver is scanned from top to bottom, and the gate line coupled to the lower gate driver is scanned from bottom to top as shown in FIGs. 9 (a) and (b).

Referring to FIGs. 9 (a) and (b), LCD driving methods will be described according to third and fourth embodiments of the present invention.

The gate lines are scanned in the direction from the edges of the panels of the upper and lower LCDs to the boundaries where the two panels

meet. That is, according to the third embodiment of the present invention as shown in FIG. 9 (a), the gate lines are scanned from the edges of the upper and lower LCD panels to the boundaries where the two panels meet, and pixel voltages with different polarities are supplied to the two pixels adjacent to the boundaries. According to the fourth embodiment of the present invention as shown in FIG. 9 (b), the gate lines are scanned from the edges of the upper LCD panel and the lower LCD panel to the boundaries where the two panels meet, and pixel voltages with identical polarities are supplied to the two pixels adjacent to the boundaries.

In order to drive the gate lines using the methods of the third and fourth embodiments of the present invention, the upper frame memory 410 in FIG. 3 transmits the image data to the upper data driver 210 in the same sequence as written, and the lower frame memory 420 transmits the image data to the lower data driver 220 in a reverse sequence of the order in which the image data are written. The upper gate driver 310 and the lower gate driver 320 respectively output gate-ON signals in sequence from the first gate line G1 of the upper gate line block and from the last gate line G2m of the lower gate line block. Other driving procedures in the methods of the third and fourth embodiments are identical to those described with reference to FIG. 3.

When driving the LCD according to the third and fourth embodiments of the present invention, the pixels of the two pixel rows at the boundaries are affected in the same direction by the voltage provided to the data lines. Therefore, since a difference in the amount of light permeating the liquid crystal material on the pixels of the boundaries is small, the brightness on the

boundaries becomes almost uniform. Consequently, the conventional line patterns generated on the boundaries where the upper panel and the lower panel meet do not appear.

As noted above, according to the present invention, the non-uniform
5 brightness phenomenon can be prevented by making the scanning direction of
the gate lines of the upper panel opposite to that of the gate lines of the lower
panel.

While this invention has been described in connection with what is
presently considered to be the most practical and preferred embodiment, it is to
10 be understood that the invention is not limited to the disclosed embodiments,
but, on the contrary, is intended to cover various modifications and equivalent
arrangements included within the spirit and scope of the appended claims.

WHAT IS CLAIMED IS:

1. A liquid crystal display (LCD), comprising:
 - a first gate line block including a plurality of first gate lines transmitting scanning signals, said first gate line block scanning in a first direction;
 - 5 a second gate line block including a plurality of second gate lines transmitting scanning signals, said second gate line block scanning in a second direction;
 - a plurality of first data lines transmitting image signals and crossing the first gate lines of said first gate line block;
 - 10 a plurality of second data lines transmitting image signals and crossing the second gate lines of said second gate line block; and
 - a plurality of pixels configured in a matrix pattern and defined by the gate lines and the data lines, said pixels including switching elements coupled to the gate lines and the data lines,
 - 15 wherein the first direction is opposite to the second direction and the first data lines are separated from the second data lines.

2. The LCD of claim 1, wherein the number of the first gate lines is equal to the number of the second gate lines.

3. The LCD of claim 2, wherein the first gate lines and the second gate lines are simultaneously scanned.

4. A liquid crystal display (LCD), comprising:
 - an LCD panel including:
 - a first gate line block having a plurality of first gate lines;

a second gate line block having a plurality of second gate lines,
said second gate line block formed beneath said first gate line block;

5 a plurality of first data lines crossing and separated from the first
gate lines of said first gate line block;

10 a plurality of second data lines crossing and separated from the
second gate lines of said second gate line block; and

15 a plurality of pixels formed by areas defined by the gate lines and
the data lines, and arrayed in a matrix pattern, the pixels having
switching elements coupled to the gate lines and the data lines, and
common electrodes to which common voltage is supplied;

20 a first data driver supplying data voltages, which contain image signals,
to the first data lines;

25 a second data driver supplying data voltages, which contain image
signals, to the second data lines;

30 a first gate driver supplying scanning signals to the gate lines of said first
gate line block;

35 a second gate driver supplying scanning signals to the gate lines of said
second gate line block in a scanning direction opposite to that of said first gate
driver;

40 a first frame memory that receives and writes external image signals in
synchronization with the write clock signals and outputs the image signals to
the first data driver in synchronization with the read clock signals; and

a second frame memory that receives and writes external image signals in synchronization with the write clock signals and outputs the image signals to the second data driver in synchronization with the read clock signals.

5. The LCD of claim 4, wherein the number of the first gate lines is equal
5 to the number of the second gate lines.

6. The LCD of claim 5, wherein said first gate driver and said second gate driver scan simultaneously.

7. The LCD of claim 5, wherein polarities of the data voltages supplied to
10 the pixels coupled to adjacent gate lines of said first gate line block are
opposite to each other with respect to the common voltage, and the polarities of
the data voltages supplied to the pixels coupled to the neighboring gate lines of
said second gate line block are opposite to each other with respect to the
common voltage.

8. The LCD of claim 7, wherein said first gate driver sequentially supplies
15 the scanning signals to the gate lines from the last gate line to the first gate line
of said first gate line block, and said second gate driver sequentially supplies
the scanning signals to the gate lines from the first gate line to the last gate line
of said second gate line block.

9. The LCD of claim 8, wherein said first frame memory outputs to said
20 first data driver the image signals in a reverse order to which the image signals
are written in, and said second frame memory outputs to said second data
driver in the same order as the image signals are written in.

10. The LCD of claim 9, wherein the polarity of the common voltage, with
respect to the data voltage supplied to the pixels coupled to the last gate line of

said first gate line block, is opposite to that of the common voltage, with respect to the data voltage supplied to the pixels coupled to the first gate line of said second gate line block on the identical pixel column.

11. The LCD of claim 9, wherein the polarity of the common voltage, with
5 respect to the data voltage supplied to the pixels coupled to the last gate line of
said first gate line block, is identical to that of the common voltage, with respect
to the data voltage supplied to the pixels coupled to the first gate line of said
second gate line block on the identical pixel column.

12. The LCD of claim 7, wherein said first gate driver sequentially
10 supplies the scanning signals to the gate lines from the first gate line to the last
gate line of said first gate line block, and the second gate driver sequentially
supplies the scanning signals to the gate lines from the last gate line to the first
gate line of said second gate line block.

13. The LCD of claim 12, wherein said first frame memory outputs to
said first data driver, the image signals, in the same order as the image signals
are written, and said second frame memory outputs to said second data driver
the image signals, which are written in a reverse order as the image signals are
written.

14. The LCD of claim 13, wherein the polarity of the common voltage,
20 with respect to the data voltage supplied to the pixels coupled to the last gate
line of said first gate line block, is opposite to that of the common voltage, with
respect to the data voltage supplied to the pixels coupled to the first gate line of
said second gate line block on the identical pixel column.

15. The LCD of claim 13, wherein the polarity of the common voltage with respect to the data voltage supplied to the pixels coupled to the last gate line of said first gate line block, is identical to that of the common voltage, with respect to the data voltage supplied to the pixels coupled to the first gate line of 5 the second gate line block on the identical pixel column.

16. A method for driving a liquid crystal display (LCD) including a first gate line block having a plurality of first gate lines; a second gate line block formed beneath the first gate line block and having a plurality of second gate lines; a plurality of first data lines crossing and separated from the first gate 10 lines of the first gate line block; and a plurality of second data lines crossing and separated from the second gate lines of the second gate line block, comprising the steps of:

providing sequentially scanning signals to the first gate line of the first gate line block;

15 providing sequentially scanning signals to the second gate line of the second gate line block in a scanning direction opposite to that of the first gate line block; and

supplying data voltages, which contain image signals, to the first and second data lines so that the data voltages are supplied to the pixels coupled to 20 the gate lines to which the scanning signals are provided.

17. The method of claim 16, wherein the scanning signals are sequentially provided to the first gate line block from the last gate line to the first gate line, and to the second gate line block from the first gate line to the last gate line.

18. The method of claim 17, wherein the method further comprises the steps of:

writing the image signals to be provided to the first data line to the first frame memory;

5 writing the image signals to be provided to the second data line to the second frame memory;

outputting the image signals to the first data lines in a reverse order as the image signals are written to the first frame memory; and

10 outputting the image signals to the second data lines in the same order as the image signals are written to the second frame memory.

19. The method of claim 16, wherein the scanning signals are sequentially provided to the first gate line block from the first gate line to the last gate line, and to the second gate line block from the last gate line to the first gate line.

15 20. The method of claim 19, wherein the method further comprises the steps of:

writing the image signals to be provided to the first data line to the first frame memory;

writing the image signals to be provided to the second data line to the second frame memory;

20 outputting the image signals to the first data lines in the same order as the image signals are written to the first frame memory; and

outputting the image signals to the second data lines in a reverse opposite order as the image signals are written to the second frame memory.

ABSTRACT OF THE DISCLOSURE

Disclosed is a liquid crystal display (LCD). An LCD panel is divided into upper and lower panels, and a scanning direction of gate lines of the upper panel is opposite to that of gate lines of the lower panel. The upper panel

5 includes an upper gate line block having a first gate line formed in the horizontal direction and transmits scanning signals, and upper data lines that cross the first gate line and transmit image signals. And the lower panel includes a lower gate line block having a second gate line, and lower data lines that cross the second gate line and are separated from the upper data lines.

10 Upper and lower gate drivers that provide scanning signals to the gate lines of the upper and lower gate line blocks are located on the sides of the upper and lower panels, respectively. The upper and lower gate drivers supply the scanning signals to the gate lines in sequentially opposite directions. According to the present invention, the non-uniform brightness phenomenon can be
15 prevented by making the scanning direction of the gate lines of the upper panel opposite to that of the gate lines of the lower panel.
